

# PARVOVIRUS

FLAME LECTURE: 102

STELLER 11.16.18

# LEARNING OBJECTIVES

- ▶ To discuss the potential impact of Parvovirus on the gravid patient and the fetus/newborn, as well as the impact of pregnancy, and the appropriate initial evaluation
- ▶ Prerequisites:
  - ▶ NONE

## BACKGROUND

- ▶ Parvovirus B19 is a small, single-stranded DNA virus that infects **ONLY** humans
- ▶ Characterized by lacy reticular rash (*aka erythema infectiosum, or Fifth disease*)

## BACKGROUND

- ▶ Self-limited
- ▶ Lasts 7-10 days
- ▶ Also manifested by fever, HA, malaise → joint pain and swelling
- ▶ 20-30% of patients have no symptoms

## BACKGROUND

- ▶ Transmission occurs most commonly via respiratory droplets
  - ▶ More common in late Winter and Spring
  - ▶ Can be transmitted in contaminated blood or RhoGam
- ▶ Incubation period is 5-10 days after exposure
- ▶ By the time the rash is present, the patient is usually no longer contagious

## EPIDEMIOLOGY

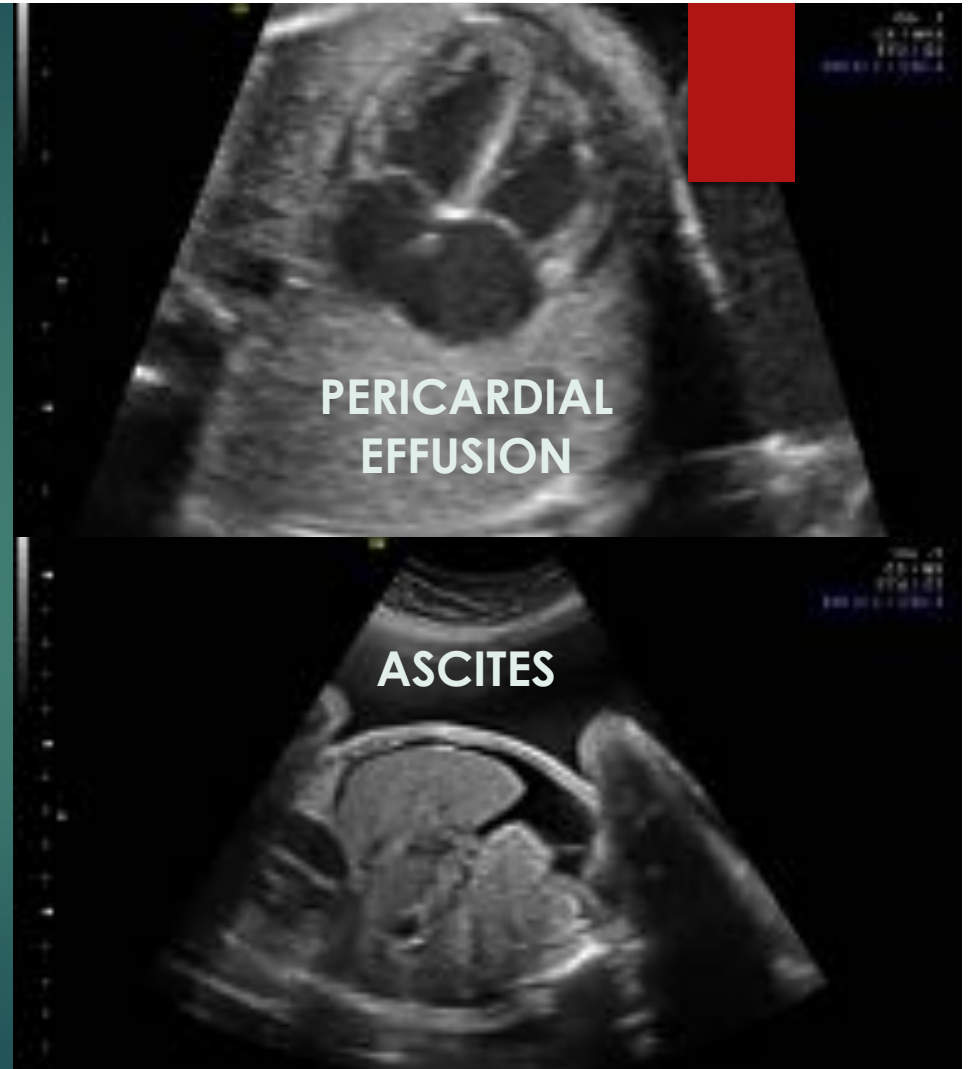

- ▶ 50-65% of adults are immune from exposure during childhood
- ▶ Primary maternal Parvovirus infection occurs in <1% of pregnancies
- ▶ An infected child will infect:
  - ▶ 50-80% of household members
  - ▶ 20-30% of classroom contacts

# PATHOPHYSIOLOGY

- ▶ PB19 preferentially infects rapidly dividing cells and is cytotoxic to **erythroid progenitor cells**
  - ▶ Rare cause of transient aplastic crisis in kids/adults with pre-existing hemoglobinopathy or chronic anemia
  - ▶ Fetal anemia → hypoxia/high output cardiac failure → impaired venous return → backup in lymph capillaries and veins → increase in interstitial fluid = **hydrops**
  - ▶ Can also infect fetal tissues → myocarditis or hepatitis which independently increase fetal interstitial fluid by exacerbating heart failure and impairing protein synthesis in the liver, respectively

## BRIEF ASIDE: WHAT IS HYDROPS?

- ▶ Abnormal fluid collections in the fetus in >1 compartment including: ascites, pleural effusion, pericardial effusion, or skin/scalp edema
  - ▶ Other frequent findings on ultrasound include placental thickening and polyhydramnios (increased amount of amniotic fluid around baby)

# FETAL EPIDEMIOLOGY

Primary maternal PB19 infection during pregnancy

1-1.5% of non-immune women

Vertical transmission

24-39% of maternal cases lead to fetal infection

Perinatal complications

3-12% of infected fetuses may develop anemia, myocarditis, hydrops, or stillbirth

**Intrauterine Fetal Demise Risk:**

**<20 weeks – 13-14.8%**

**>20 weeks – 0.5-2.3%**

# DIAGNOSIS / MANAGEMENT

If exposure OR ultrasound findings  
→ check maternal serology

IgG +  
IgM -

Immune,  
no risk

IgG -  
IgM -

Susceptible, no  
evidence of  
current infection

Repeat in 3-4  
weeks

IgG ±  
IgM +

PB19 DNA PCR (by  
amniocentesis)  
confirms diagnosis

Q1-2 wk ultrasound  
surveillance

- ▶ **IgM becomes POS 3-5 days after sx** (or 7-10 days after infection) and persists for weeks-months
- ▶ **IgG becomes POS 7 days after sx** (or 14 days after infection)
- ▶ Can also look at B19V DNA in serum/plasma/cord blood/amniotic fluid
  - ▶ but this cannot provide time course

# FETAL MANAGEMENT

- ▶ Hydrops typically develops ~2-6 weeks after seroconversion, but may occur up to 10-12 weeks after
- ▶ As a fetus becomes anemic, decreased blood viscosity triggers shunting of blood to critical organs such as the brain
  - ▶ Thus, fetal Middle Cerebral Artery (MCA) velocity studies should be monitored via ultrasound q1-2w for 10-12 wks following seroconversion to detect fetal anemia before hydrops develops
- ▶ If the MCA peak systolic velocity increases significantly, intrauterine transfusion (IUT) can be considered
  - ▶ Frequently only 1 IUT is needed
  - ▶ Occasionally RBCs and platelets may need to be transfused
- ▶ Limited evidence regarding IVIG (intravenous immunoglobulin)

# FETAL MANAGEMENT

- ▶ If no signs of hydrops or anemia by 10-12 weeks of exposure, very low likelihood they will develop
- ▶ Very few cases of fetal death have been reported in the absence of hydrops
- ▶ If compromise noted after 34 weeks → DELIVER
  - ▶ Otherwise delivery can be delayed until 37-39 weeks depending upon fetal status
- ▶ Long-term neurodevelopmental outcomes in fetus are conflicting
  - ▶ With some limited evidence that Parvovirus and/or anemia necessitating IUT may be associated with worse neurologic outcomes

# MATERNAL MANAGEMENT

- ▶ Frequent handwashing
- ▶ Expectant management
  - ▶ No medical treatment available
- ▶ No vaccine available
- ▶ Screen mom for chronic anemia +/- hemoglobinopathy to stratify risk of aplastic crisis
- ▶ If fetal hydrops develops, monitor mom for mirror syndrome

## BRIEF ASIDE: MIRROR SYNDROME?

- ▶ Mothers start to mirror their hydropic fetus
  - ▶ 80-90% have edema
  - ▶ 60% have hypertension
  - ▶ 40% have proteinuria
  - ▶ 21% have pulmonary edema
- ▶ It also mimics pre-eclampsia with signs above and symptoms of headache and visual changes as well
- ▶ IUT and/or labor induction are only treatment options
